5                    METHODS AND COMPOSITIONS FOR DETECTING DIHYDROPYRIMIDINE  
                      DEHYDROGENASE SPLICING MUTATIONS

                      TECHNICAL FIELD OF THE INVENTION

                      The present invention relates to methods and compositions for detecting  
                      splicing defects in the dihydropyrimidine dehydrogenase gene. The methods and  
10    compositions are useful for identifying persons who are at risk of a toxic reaction to the  
                      commonly employed cancer chemotherapy agent, 5-fluorouracil.

                      BACKGROUND OF THE INVENTION

                      5-Fluorouracil (5-FU) is commonly used in the treatment of cancers,  
15    including cancers of the breast, head, neck, and digestive system. The efficacy of 5-FU  
                      as a cancer treatment varies significantly among patients. Clinically significant  
                      differences in systemic clearance and systemic exposure of 5-FU are often observed. *See*,  
                      Grem, J.L. *In* Chabner, B.A. and J.M. Collins (eds.), *Cancer Chemotherapy: Principles*  
                      *and Practice*, pp. 180-224, Philadelphia, PA, Lippincott, 1990). Furthermore, 5-FU  
20    treatment is severely toxic to some patients, and has even caused death. *See*, Fleming *et al.*  
                      (1993) *Eur. J. Cancer* 29A: 740-744; Thyss *et al.* (1986) *Cancer Chemother.*  
                      *Pharmacol.* 16: 64-66; Santini *et al.* (1989) *Br. J. Cancer* 59: 287-290; Goldberg *et al.*  
                      (1988) *Br. J. Cancer* 57: 186-189; Trump *et al.* (1991) *J. Clin. Oncol.* 9: 2027-2035;  
                      and Au *et al.* (1982) *Cancer Res.* 42: 2930-2937.  
25                    Patients in whom 5-FU is severely toxic typically have low levels of  
                      dihydropyrimidine dehydrogenase (DPD) activity. *See*, Tuchman *et al.* (1985) *N. Engl.*  
                      *J. Med.* 313: 245-249; Diasio *et al.* (1988) *J. Clin. Invest.* 81: 47-51; Fleming *et al.*  
                      (1991) *Proc. Am. Assoc. Cancer Res.* 32: 179; Harris *et al.* (1991) *Cancer (Phila.)* 68:  
                      499-501; Houyau *et al.* (1993) *J. Nat'l. Cancer Inst.* 85: 1602-1603; Lyss *et al.* (1993)  
30    *Cancer Invest.* 11: 239-240. Dihydropyrimidine dehydrogenase (DPD, EC 1.3.1.2) is the  
                      principal enzyme involved in the degradation of 5-FU, which acts by inhibiting  
                      thymidylate synthase. *See*, Heggie *et al.* (1987) *Cancer Res.* 47: 2203-2206; Chabner *et al.*  
                      (1989) *In* DeVita *et al.* (eds.), *Cancer - Principles and Practice of Oncology*, pp. 349-

395, Philadelphia, PA, Lippincott; Diasio *et al.* (1989) *Clin. Pharmacokinet.* 16: 215-237; Grem *et al.*, *supra*. The level of DPD activity also affects the efficacy of 5-FU treatments, as 5-FU plasma levels are inversely correlated with the level of DPD activity. See, Iigo *et al.* (1988) *Biochem. Pharm.* 37: 1609-1613; Goldberg *et al.*, *supra.*; Harris  
5 *et al.*, *supra.*; Fleming *et al.*, *supra.* In turn, the efficacy of 5-FU treatment of cancer is correlated with plasma levels of 5-FU.

In addition to its 5-FU degrading activity, DPD is also the initial and rate limiting enzyme in the three-step pathway of uracil and thymine catabolism, leading to the formation of  $\beta$ -alanine and  $\beta$ -aminobutyric acid, respectively. See, Wasternack *et al.*  
10 (1980) *Pharm. Ther.* 8: 629-665. DPD deficiency is associated with inherited disorders of pyrimidine metabolism, clinically termed thymine-uraciluria. See, Bakkeren *et al.* (1984) *Clin. Chim. Acta.* 140: 247-256. Clinical symptoms of DPD deficiency include a nonspecific cerebral dysfunction, and DPD deficiency is associated with psychomotor retardation, convulsions, and epileptic conditions. See, Berger *et al.* (1984) *Clin. Chim.*  
15 *Acta* 141: 227-234; Wadman *et al.* (1985) *Adv. Exp. Med. Biol.* 165A: 109-114; Wilcken *et al.* (1985) *J. Inherit. Metab. Dis.* 8 (Suppl. 2): 115-116; van Gennip *et al.* (1989) *Adv. Exp. Med. Biol.* 253A: 111-118; Brockstedt *et al.* (1990) *J. Inherit. Metab. Dis.* 12: 121-124; and Duran *et al.* (1991) *J. Inherit. Metab. Dis.* 14: 367-370. Biochemically, patients having DPD deficiency have an almost complete absence of DPD  
20 activity in fibroblasts (see, Bakkeren *et al.*, *supra*) and in lymphocytes (see, Berger *et al.*, *supra* and Piper *et al.* (1980) *Biochim. Biophys. Acta* 633: 400-409. These patients typically have a large accumulation of uracil and thymine in their cerebrospinal fluid (see, Bakkeren *et al.*, *supra.*) and urine (see, Berger *et al.*, *supra.*; Bakkeren *et al.*, *supra.*; Brockstedt *et al.*, *supra.*; and Fleming *et al.* (1992) *Cancer Res.* 52: 2899-2902).

25       Familial studies suggest that DPD deficiency follows an autosomal recessive pattern of inheritance. See, Diasio *et al.*, (1988) *supra*. Up to three percent of the general human population are estimated to be putative heterozygotes for DPD deficiency, as determined by enzymatic activity in lymphocytes. See, Milano and Eteinne (1994) *Pharmacogenetics*. This suggests that the frequency of homozygotes for DPD  
30 deficiency may be as high as one person per thousand.

DPD has been purified from liver tissue of rats (see, Shiotani and Weber (1981) *J. Biol. Chem.* 256: 219-224; Fujimoto *et al.* (1991); *J. Nutr. Sci. Vitaminol.* 37:

89-98], pig [Podschun *et al.* (1989) *Eur. J. Biochem.* 185: 219-224), cattle (*see*, Porter *et al.* (1991) *J. Biol. Chem.* 266: 19988-19994), and humans (*see*, Lu *et al.* (1992) *J. Biol. Chem.* 267: 1702-1709). The pig enzyme contains flavins and iron-sulfur prosthetic groups and exists as a homodimer with a monomer Mr of about 107,000 (*see*, Podschun *et al.*, *supra.*). Since the enzyme exhibits a nonclassical two-site ping-pong mechanism, it appears to have distinct binding sites for NADPH/NADP and uracil/5,6-dihydrouracil (*see*, Podschun *et al.* (1990) *J. Biol. Chem.* 265: 12966-12972). An acid-base catalytic mechanism has been proposed for DPD (*see*, Podschun *et al.* (1993) *J. Biol. Chem.* 268: 3407-3413).

10           The DPD cDNA is described in copending U.S. application SN 08/304,309. Recently, DPD mRNA from patients lacking dihydropyrimidine activity was found to lack an exon which encodes a 165 base pair sequence found in the wild-type DPD cDNA. *See*, Meinsma *et al.* (1995) *DNA and Cell Biology* 14(1): 1-6.

15           Because an undetected DPD deficiency poses a significant danger to a cancer patient who is being treated with 5-FU, a great need exists for a simple and accurate test for DPD deficiency. Such a test will also facilitate diagnosis of disorders that are associated with DPD deficiency, such as uraciluria. The present invention provides such a test, thus fulfilling these and other needs.

## 20                           SUMMARY OF THE INVENTION

Particular mutations in the dihydropyrimidine dehydrogenase gene are described herein which lead to loss of dihydropyrimidine dehydrogenase activity. The mutations result in a loss of the amino acids from 581-635 of the protein encoded by the gene due to a splicing defect. The splicing defect results in the loss of an exon encoding  
25   the missing amino acids. The assays and compositions of the invention detect the splicing defect in the genomic DNA which results in the loss of the exon.

A variety of assays for detecting splicing defect mutations in patients are provided. The assays determine whether RNA encoded by genomic DNA is competent to be spliced to produce mRNA with nucleic acids encoding the exon which corresponds to  
30   amino acids from 581-635 of the wild-type protein. For example, sequencing, PCR, LCR, and oligonucleotide array based assays are used to detect the mutations.

In one class of embodiments, the methods comprise the step of determining whether a nucleic acid encoding an mRNA for the dihydropyrimidine dehydrogenase gene has an exon corresponding to amino acids 581-635 of a corresponding wild-type dihydropyrimidine dehydrogenase mRNA. This determination is performed in

5 sequencing, PCR, LCR, and oligonucleotide array based hybridization assays. For example, in one class of PCR based assays, the intronic genomic DNA encoding the dihydropyrimidine dehydrogenase in the region flanking the exon which encodes amino acids 581-635 is hybridized to a set of PCR primers for amplification and analysis of the intron-exon splice boundaries.

10 Example primers which are used for amplifying the splice regions include DELF1 and DELR1. Similar primers which hybridize to the same sites, or to sites proximal to the primer binding sites are also used.

One particular mutation which results in an abnormal dihydropyrimidine dehydrogenase gene phenotype is the conversion of a G to an A residue at the 3' GT  
15 splice site of the exon which encodes amino acids 581-635 of the corresponding wild-type protein. The 3' wild-type splice site is recognized by restriction endonucleases which recognize the Mae II cleavage site. The ability of the cleavage site to be cleaved by restriction endonucleases which recognize the Mae II site is used to distinguish wild-type from abnormal dihydropyrimidine dehydrogenase genomic DNAs. For example, a region  
20 including the mutation is amplified by PCR, and the PCR products cleaved by Mae II. This results in the cleavage of nucleic acids amplified by the wild-type gene, but mutant sequences are not amplified.

In addition to PCR detection methods, nucleic acid arrays are used to discriminate single base-pair mismatches, or to directly sequence DNA by hybridization  
25 to arrays. The sequence of the splice site is also determined by standard or PCR sequencing of the site, *e.g.*, using primers which flank the site in a *pol I* or *saq* PCR based sequencing assay.

In addition to methods and compositions for abnormal dihydropyrimidine dehydrogenase gene detection, the invention provides kits for practicing the methods.  
30 Typically, the kit contains a first PCR primer which binds to DNA 3' of a splice site in the genomic DNA for dihydropyrimidine dehydrogenase gene for an exon encoding amino acids 581-635, and a second PCR primer which binds to DNA 5' of a splice site in the

genomic DNA for dihydropyrimidine dehydrogenase gene for an exon encoding amino acids 581-635. The kit optionally contains other components such as instructions for the detection of an abnormal dihydropyrimidine dehydrogenase gene, restriction enzymes such as Mae II, PCR or other *in vitro* amplification reagents (buffers, enzymes, salts and the like), oligonucleotide array detection chips and the like.

#### DETAILED DESCRIPTION OF THE DRAWING

Figure 1 provides genomic sequence from the DPD gene in the region of a splicing mutant which leads to the loss of an exon in the mRNA which encodes amino acids 581-635. The primer binding sites for DELF-1 and DELR1 are indicated. The primer binding site for DPD15F and DPD15R (*see*, Meinsma *et al.* (1995) *DNA and Cell Biology* 14(1): 1-6) are also indicated. The Mae II site at the 3' splice junction is indicated. In a mutant form, the G nucleotide at the 3' splice junction (residue 434) is mutated to an A nucleotide.

Figure 2 provides further details of PCR reaction components for amplifying the region of a splicing site mutant. The exon is underlined. The splice site which is polymorphic is in bold text.

Figure 3 is a schematic of the splicing product of the mutant DPD gene.

Figure 4 is a schematic representation of an example strategy for amplifying an exon deleted in mutant Dpd mRNA from the genomic DNA for the gene. The restriction endonuclease Mae II produces fragments of 278 bp and 131 bp in the wild-type allele. A point mutation at the donor splicing consensus sequence (GT to AT) destroys the restriction site, and thus, the mutant form remains undigested (409 bp).

#### DEFINITIONS

Unless defined otherwise, all technical and scientific terms used herein have the same meaning as commonly understood by one of ordinary skill in the art to which this invention belongs. Singleton *et al.* (1994) *Dictionary of Microbiology and Molecular Biology*, second edition, John Wiley and Sons (New York); Walker (ed) (1988) *The Cambridge Dictionary of Science and Technology*, The press syndicate of the University of Cambridge, NY; and Hale and Marham (1991) *The Harper Collins Dictionary of Biology* Harper Perennial, NY provide one of skill with a general

dictionary of many of the terms used in this invention. Although any methods and materials similar or equivalent to those described herein can be used in the practice or testing of the present invention, preferred methods and materials are described. For purposes of the present invention, the following terms are defined below.

5           The term "nucleic acid" refers to deoxyribonucleotides, ribonucleotides, and polymers thereof in either single- or double-stranded form, and unless specifically limited, encompasses known analogues of natural nucleotides that hybridize to nucleic acids in a manner similar to naturally occurring nucleotides. Unless otherwise indicated, a particular reference nucleic acid sequence implicitly encompasses conservatively  
10 modified variants thereof (*i.e.*, sequence variants that hybridize with the reference nucleic acid, that encode the same amino acid sequence as the reference nucleic acid, or that encode amino acid sequences containing conservative amino acid substitutions as compared to the amino acid sequence encoded by the reference nucleic acid), and complementary sequences and as well as the sequence explicitly indicated.

15           The term "wild type," when applied to a gene, nucleic acid or gene product, especially a protein and/or biological property, denotes a gene, gene product, protein, or biological property predominantly found in nature. "Mutant" proteins, nucleic acids and the like occur less frequently and are often associated with loss or alteration of biological activity and a diseased state.

20           The term "dihydropyrimidine dehydrogenase gene" refers to a naturally occurring nucleic acid that encodes a protein that has dihydropyrimidine dehydrogenase activity, or that is specifically recognized by antibodies specific for dihydropyrimidine dehydrogenase. The term encompasses both wild-type and mutant genes.

25           "Intron-exon boundary" denotes a sequence of a gene present in or derived from a genomic DNA, wherein the sequence comprises intron sequences that are absent in a mature mRNA transcript, contiguous to exon regions that are present in the mature mRNA transcript.

30           A "splicing defect" is a failure to correctly remove an intron or to correctly connect two exons in the mature mRNA transcript, which often are the result of sequence mutations in the intron-exon boundary.

          "Stringency" relates to the conditions under which hybridization and annealing take place. Low stringency hybridization and annealing conditions permit the

annealing of complementary nucleic acids that contain mismatched nucleic acids. As the stringency is raised, annealing of sequences containing mismatched nucleic acids is disfavored. Conditions which result in low or high stringency levels are known in the art (e.g., increasing the annealing temperature raises the stringency).

- 5           An extensive guide to the hybridization of nucleic acids is found in Tijssen (1993) *Laboratory Techniques in Biochemistry and Molecular Biology--Hybridization with Nucleic Acid Probes* part I chapter 2 "overview of principles of hybridization and the strategy of nucleic acid probe assays", Elsevier, New York. Generally, highly stringent hybridization and wash conditions are selected to be about 5° C lower than the thermal  
10 melting point ( $T_m$ ) for the specific sequence at a defined ionic strength and pH. The  $T_m$  is the temperature (under defined ionic strength and pH) at which 50% of the target sequence hybridizes to a perfectly matched probe. Very stringent conditions are selected to be equal to the  $T_m$  for a particular probe.

- Methods of alignment of sequences for comparison and determination of  
15 whether two sequences bind the same target are well known in the art. Optimal alignment of sequences for comparison may be conducted by the local homology algorithm of Smith and Waterman (1981) *Adv. Appl. Math.* 2: 482; by the homology alignment algorithm of Needleman and Wunsch (1970) *J. Mol. Biol.* 48: 443; by the search for similarity method of Pearson and Lipman (1988) *Proc. Natl. Acad. Sci. USA*  
20 85: 2444; by computerized implementations of these algorithms (including, but not limited to CLUSTAL in the PC/Gene program by Intelligenetics, Mountain View, California, GAP, BESTFIT, FASTA, and TFASTA in the Wisconsin Genetics Software Package, Genetics Computer Group (GCG), 575 Science Dr., Madison, Wisconsin, USA); the CLUSTAL program is well described by Higgins and Sharp (1988) *Gene*, 73:  
25 237-244 and Higgins and Sharp (1989) *CABIOS* 5: 151-153; Corpet, *et al.* (1988) *Nucleic Acids Research* 16, 10881-90; Huang, *et al.* (1992) *Computer Applications in the Biosciences* 8, 155-65, and Pearson, *et al.* (1994) *Methods in Molecular Biology* 24, 307-31. Alignment is also often performed by inspection and manual alignment.

- A "restriction endonuclease which recognizes a Mae II cleavage site" is a  
30 DNA endonuclease that recognizes and cleaves a nucleic acid which is cleaved by the restriction endonuclease Mae II (*see also*, Figure 1).

A "PCR primer" is one of a pair of oligonucleotides complementary to a subregion of a nucleic acid that, when annealed to the nucleic acid, generates a double stranded sequence which supports nucleic acid synthesis by primer extension in a PCR reaction.

5

## DETAILED DISCUSSION OF THE INVENTION

The present invention provides compositions, methods and kits for detecting point mutations in DPD nucleic acid samples. Genetic amplification techniques are used to detect point mutations in a splicing region of the DPD gene which results in the deletion of an exon in the DPD gene product, and causes one form of DPDD (DPD deficiency).

10

### Isolation of nucleic acid samples

To amplify a target intron-exon boundary in a sample, the nucleic acid encoding the sequence is made accessible to the components of the amplification system. In general, this accessibility is ensured by isolating the nucleic acids from the sample, however, isolation is optional (methods for amplifying nucleic acids, *e.g.*, by PCR from whole cells are known and appropriate). A variety of techniques for extracting nucleic acids from biological samples are known in the art. For example, see those described in Rotbart *et al.*, 1989, in *PCR Technology* (Erich ed., Stockton Press, New York) and Han *et al.*, 1987, *Biochemistry* 26:1617-1625. The methods described by Fries *et al.*, *Am. J. Med. Genet.*, 46:363-368 (1993), are also useful.

15

20

Nucleic acids are isolated from cell or tissue samples from patients, and from cell culture. The culture of cells used in conjunction with the present invention, including cell lines and cultured cells from tissue or blood samples, including stem cells is well known in the art. Freshney (*Culture of Animal Cells, a Manual of Basic Technique, third edition* Wiley-Liss, New York (1994)) and the references cited therein provides a general guide to the culture of cells. See also, Kuchler *et al.* (1977) *Biochemical Methods in Cell Culture and Virology*, Kuchler, R.J., Dowden, Hutchinson and Ross, Inc, and Inaba *et al.* (1992) *J. Exp. Med.* 176, 1693-1702.

25

30

The methods of the present invention are employed for analyzing nucleic acid from a variety of different tissues, such as tissues samples (*e.g.*, fetal and amniotic fluid tissue) and patient-derived tissue culture cell lines (*e.g.*, fibroblast cell lines). Where

blood cells are used, whole blood should be drawn with an anticoagulant in a sealed vacuum tube kept separated from other samples and handled with clean gloves. For best results, blood is processed immediately after collection; if this is impractical, it is kept in a sealed container until use. Cells in other physiological fluids, such as amniotic fluid, are also optionally assayed. When using any of these fluids, the cells in the fluid are typically separated from the fluid component by centrifugation.

Several methods are particularly well suited for use in amplifying target regions. The choice between these methods is typically governed by the size of the sample which is available for testing. One method is crude extraction which is useful for relatively large samples. Briefly, mononuclear cells from samples of blood, buffy coat, amniocytes from amniotic fluid, cultured chorionic villus cells, or the like are isolated by standard procedures (*see*, Freshney, *supra*). If testing is not performed immediately after sample collection, aliquots of cells can be pelleted in sterile Eppendorf tubes and the dry pellet frozen at -20°C or colder until use.

The blood cells are resuspended (typically from 10 to about 10<sup>6</sup> nucleated cells per 100  $\mu$ l to 1 ml) in a buffer of 50 mM Tris-HCl (pH 8.3), 50 mM KCl 1.5 mM MgCl<sub>2</sub>, 0.5% Tween 20, 0.5% NP40 supplemented with 100  $\mu$ g/ml of proteinase K. After incubating at 56°C for 2 hr, the cells are heated to 95°C for 10 min to inactivate the proteinase K and immediately moved to wet ice (snap-cool). If gross aggregates are present, another cycle of digestion in the same buffer should be undertaken. Ten  $\mu$ l of this extract is generally used for amplification.

When extracting DNA from tissues, *e.g.*, chorionic villus cells or confluent cultured cells, the amount of the above mentioned buffer with proteinase K varies according to the size of the tissue sample. The extract is incubated for 4-10 hrs at 50°-60°C and then at 95°C for 10 minutes to inactivate the proteinase. During longer incubations, fresh proteinase K should be added after about 4 hr at the original concentration.

When the sample contains a small number of cells, extraction may be accomplished, *e.g.*, by methods as described in Higuchi, "Simple and Rapid Preparation of Samples for PCR", in *PCR Technology*, Ehrlich, H.A. (ed.), Stockton Press, New York, which is incorporated herein by reference.

A relatively easy procedure for extracting DNA for amplification is a "salting out" procedure adapted from the method described by Miller *et al.*, *Nucleic Acids Res.*, 16:1215 (1988). Mononuclear cells are separated on a Ficoll-Hypaque gradient. The cells are resuspended in 3 ml of lysis buffer (10 mM Tris-HCl, 400 mM NaCl, 2 mM Na<sub>2</sub>EDTA, pH 8.2). Fifty  $\mu$ l of a 20 mg/ml solution of proteinase K and 150  $\mu$ l of a 20% SDS solution are added to the cells and then incubated at 37°C overnight. Rocking the tubes during incubation will improve the digestion of the sample. If the proteinase K digestion is incomplete after overnight incubation (fragments are still visible), an additional 50  $\mu$ l of the 20 mg/ml proteinase K solution is mixed in the solution and incubated for another night at 37°C on a gently rocking or rotating platform. Following adequate digestion, one ml of a 6M NaCl solution is added to the sample and vigorously mixed. The resulting solution is centrifuged for 15 minutes at 3000 rpm. The pellet contains the precipitated cellular proteins, while the supernatant contains the DNA. The supernatant is removed to a 15 ml tube that contains 4 ml of isopropanol. The contents of the tube are mixed gently until the water and the alcohol phases have mixed and a white DNA precipitate has formed. The DNA precipitate is removed and dipped in a solution of 70% ethanol and mixed gently. The DNA precipitate is removed from the ethanol and air dried. The precipitate is placed in distilled water and dissolved.

Kits are also commercially available for the extraction of high-molecular weight (*i.e.*, genomic) DNA. These kits include Genomic Isolation Kit A.S.A.P. (Boehringer Mannheim, Indianapolis, IN), Genomic DNA Isolation System (GIBCO BRL, Gaithersburg, MD), Elu-Quik DNA Purification Kit (Schleicher & Schuell, Keene, NH), DNA Extraction Kit (Stratagene, La Jolla, CA), TurboGen Isolation Kit (Invitrogen, San Diego, CA), and the like. Use of these kits according to the manufacturer's instructions is generally acceptable for purification of DNA when practicing the methods of the present invention.

The concentration and purity of the extracted DNA may be determined by spectrophotometric analysis of the absorbance of a diluted aliquot at 260 nm and 280 nm. Either 10  $\mu$ l of crude extract, or 1  $\mu$ g of purified DNA by the alternate methods are used for amplification.

### PCR Amplification of the Intron-Exon Boundaries of the DPD gene

The nucleic acids at intron-exon boundaries are typically amplified when determining whether a splicing defect is present in a sample. In a preferred embodiment, amplification is performed by the PCR method. Although the PCR process is well known in the art (see, U.S. Patent Nos. 4,683,195; 4,683,202; and 4,965,188, each of which is incorporated herein by reference) and although commercial vendors, such as Roche Molecular Systems, sell PCR reagents and publish PCR protocols, some general PCR information is provided below for purposes of clarity and full understanding of the invention for those unfamiliar with the PCR process.

In brief, a DNA sample is heat denatured to separate the individual complementary strands and annealed in the presence a pair of oligonucleotide primers which are complementary to sequences present on opposite stands and located on either side of the sequence to be detected. The PCR mixture is then subjected to repeated cycles of DNA synthesis, denaturation and reannealing.

The first step of each cycle of the PCR involves the separation of the nucleic acid duplex formed by the primer extension. Once the strands are separated, the next step in PCR involves hybridizing the separated strands with primers that flank the target sequence. The primers are then extended to form complementary copies of the target strands. For successful PCR amplification, the primers are designed so that the position at which each primer hybridizes along a duplex sequence is such that an extension product synthesized from one primer, when separated from the template (complement), serves as a template for the extension of the other primer. The cycle of denaturation, hybridization, and extension is repeated as many times as necessary to obtain the desired amount of amplified nucleic acid.

In a preferred embodiment of the PCR process, strand separation is achieved by heating the reaction to a sufficiently high temperature for an sufficient time to cause the denaturation of the duplex but not to cause an irreversible denaturation of the polymerase (see U.S. Patent No. 4,965,188). Typical heat denaturation involves temperatures ranging from about 80°C to 105°C for times ranging from seconds to minutes. Strand separation, however, can be accomplished by any suitable denaturing method including physical, chemical, or enzymatic means. Strand separation may be induced by a helicase, for example, or an enzyme capable of exhibiting helicase activity. For example, the enzyme

RecA has helicase activity in the presence of ATP. The reaction conditions suitable for strand separation by helicases are known in the art (see Kuhn Hoffman-Berling, 1978, *CSH-Quantitative Biology* 43:63-67; and Radding, 1982, *Ann. Rev. Genetics* 16:405-436, both of which are incorporated herein by reference).

5           Template-dependent extension of primers in PCR is catalyzed by a polymerizing agent in the presence of adequate amounts of four deoxyribonucleoside triphosphates (typically dATP, dGTP, dCTP, and dTTP) in a reaction medium comprised of the appropriate salts, metal cations, and pH buffering system. Suitable polymerizing agents are enzymes known to catalyze template-dependent DNA synthesis. In some  
10 instances, DPD-encoding RNA may be used as the initial template for primer extension is RNA. Polymerizing agents suitable for synthesizing a complementary, DNA (cDNA) sequence from the RNA template are reverse transcriptase (RT), such as avian myeloblastosis virus RT, Moloney murine leukemia virus RT, or *Thermus thermophilus* (*Tth*) DNA polymerase, a thermostable DNA polymerase with reverse transcriptase activity  
15 marketed by Roche Molecular Systems. Typically, the RNA template is heat degraded during the first denaturation step after the initial reverse transcription step leaving only DNA template. Suitable polymerases for use with a DNA template include, for example, *E. coli* DNA polymerase I or its Klenow fragment, *T<sub>4</sub>* DNA polymerase, *Tth* polymerase, and *Taq* polymerase, a heat-stable DNA polymerase isolated from *Thermus aquaticus* and  
20 commercially available from Roche Molecular Systems. The latter enzyme is widely used in the amplification and sequencing of nucleic acids. The reaction conditions for using *Taq* polymerase are known in the art and are described in Innis, *supra*.

          When RNA is amplified, an initial reverse transcription (RT) step is carried out to create a DNA copy (cDNA) of the RNA. PCT patent publication No. WO  
25 91/09944, published July 11, 1991, incorporated herein by reference, describes high-temperature reverse transcription by a thermostable polymerase that also functions in PCR amplification. High-temperature RT provides greater primer specificity and improved efficiency. A "homogeneous RT-PCR" in which the same primers and polymerase suffice for both the reverse transcription and the PCR amplification steps, and  
30 the reaction conditions are optimized so that both reactions occur without a change of reagents is also available. *Thermus thermophilus* DNA polymerase, a thermostable DNA polymerase that can function as a reverse transcriptase, is used for all primer extension

steps, regardless of template. Both processes can be done without having to open the tube to change or add reagents; only the temperature profile is adjusted between the first cycle (RNA template) and the rest of the amplification cycles (DNA template).

The PCR method can be performed in a step-wise fashion, where after each  
5 step new reagents are added, or in a fashion where all of the reagents are added simultaneously, or in a partial step-wise fashion, where fresh or different reagents are added after a given number of steps. For example, if strand separation is induced by heat, and the polymerase is heat-sensitive, then the polymerase is added after every round of strand separation. However, if, for example, a helicase is used for denaturation, or if  
10 thermostable polymerase is used for extension, then all of the reagents are added initially, or, alternatively, if molar ratios of reagents are of consequence to the reaction, the reagents may be replenished periodically as they are depleted by the synthetic reaction.

Those skilled in the art will know that the PCR process is most usually carried out as an automated process with a thermostable enzyme. In this process, the  
15 temperature of the reaction mixture is cycled through a denaturing region, a primer annealing region, and an extension reaction region. Alternatively, the annealing and extension temperature can be the same. Reverse transcriptase-PCR uses such a two-step temperature cycling. A machine specifically adapted for use with a thermostable enzyme is commercially available from Roche Molecular Systems.

20 Those skilled in the art will also be aware of the problems of contamination of a PCR by the amplified nucleic acid from previous reactions and nonspecific amplification. Methods to reduce these problems are provided in PCT patent application Serial No. 91/05210, filed July 23, 1991, incorporated herein by reference. The method allows the enzymatic degradation of any amplified DNA from previous reactions and  
25 reduces nonspecific amplification. The PCR amplification is carried out in the presence of dUTP instead of dTTP. The resulting double-stranded, uracil-containing product is subject to degradation by uracil N-glycosylase (UNG), whereas normal thymine-containing DNA is not degraded by UNG. Adding UNG to the amplification reaction mixture before the amplification is started degrades all uracil-containing DNA that might serve as target.  
30 Because the only source of uracil-containing DNA is the amplified product of a previous reaction, this method effectively sterilizes the reaction mixture, eliminating the problem of contamination from previous reactions (carry-over). UNG itself is rendered temporarily

inactive by heat, so the denaturation steps in the amplification procedure also serve to inactivate the UNG. New amplification products, therefore, though incorporating uracil, are formed in an effectively UNG-free environment and are not degraded.

Those practicing the present invention should note that, although the preferred embodiment incorporates PCR amplification, amplification of target sequences in a sample may be accomplished by any known method, such as ligase chain reaction (LCR), transcription amplification, and self-sustained sequence replication, each of which provides sufficient amplification so that the target sequence can be detected by nucleic acid hybridization to a probe. Persons of skill will appreciate that in methods such as LCR, primers that are complementary to the specific polymorphism or mutation are used. In this instance amplification occurs when the polymorphism (*i.e.*, point mutation) is present in the nucleic acid sample.

Alternatively, methods that amplify the probe to detectable levels can be used, such as Q $\beta$ -replicase amplification. The term "probe" encompasses, *inter alia*, the sequence specific oligonucleotides used in the above procedures; for instance, the two or more oligonucleotides used in LCR are "probes" for purposes of the present invention, even though some embodiments of LCR only require ligation of the probes to indicate the presence of an allele.

Examples of techniques sufficient to direct persons of skill through such *in vitro* amplification methods, including the polymerase chain reaction (PCR) the ligase chain reaction (LCR), Q $\beta$ -replicase amplification and other RNA polymerase mediated techniques (*e.g.*, NASBA) are found in Berger and Kimmel, *Guide to Molecular Cloning Techniques*, Methods in Enzymology volume 152 Academic Press, Inc., San Diego, CA (Berger); Sambrook et al. (1989) *Molecular Cloning - A Laboratory Manual* (2nd ed.) Vol. 1-3, Cold Spring Harbor Laboratory, Cold Spring Harbor Press, NY, (Sambrook); and *Current Protocols in Molecular Biology*, F.M. Ausubel et al., eds., Current Protocols, a joint venture between Greene Publishing Associates, Inc. and John Wiley & Sons, Inc., (1994 Supplement) (Ausubel), and in Mullis *et al.*, (1987) U.S. Patent No. 4,683,202; *PCR Protocols A Guide to Methods and Applications* (Innis *et al.* eds) Academic Press Inc. San Diego, CA (1990) (Innis); Arnheim & Levinson (October 1, 1990) *C&EN* 36-47; *The Journal Of NIH Research* (1991) 3, 81-94; (Kwoh *et al.* (1989) *Proc. Natl. Acad. Sci. USA* 86, 1173; Guatelli *et al.* (1990) *Proc. Natl. Acad. Sci. USA* 87, 1874; Lomell *et al.*

(1989) *J. Clin. Chem* 35, 1826; Landegren *et al.*, (1988) *Science* 241, 1077-1080; Van Brunt (1990) *Biotechnology* 8, 291-294; Wu and Wallace, (1989) *Gene* 4, 560; Barringer *et al.* (1990) *Gene* 89, 117, and Sooknanan and Malek (1995) *Biotechnology* 13: 563-564. Improved methods of cloning *in vitro* amplified nucleic acids are described in Wallace *et al.*, U.S. Pat. No. 5,426,039.

The present invention provides, *inter alia*, a polymorphic form of DPD. In particular, the invention provides a DPDD polymorphism wherein the G at position 434 of the gene sequence shown in Figure 1 is replaced by an A.

This particular polymorphism is detected by a variety of amplification techniques, preferably PCR as described *supra*. To detect this polymorphism by PCR, the PCR reaction is performed in the presence of primers that are complimentary to opposite strands of the genomic DNA, wherein the complementary sequences are located on either side of the point mutation. The precise sequences recognized by the primers are not critical. Typically, any pair of primers can be used as long as they (1) bracket the polymorphism, (2) are reasonably near to the polymorphism (while the primer binding sequence may be as far from the polymorphism as can support a PCR reaction, *i.e.*, 1 to about 10 kb, it is preferable that the binding sequence be within about 500 nucleotides or less, and more preferable that the binding sequence be within 100 nucleotides of the exon-intron boundary to be assayed), and (3) bind the primers with an adequate degree of specificity. It is preferable that the sequence be unique to the gene of interest. Such sequences are identified by comparing sequences as described herein. Smaller primers have a higher probability of recognizing sites outside of the desired binding site, whereas very large primers are more expensive to make; generally, a primer of about 15-20 nucleotides is adequate, and therefore preferred.

Example primers used herein are DELF1, which hybridizes to nucleic acids corresponding to nucleotide 154 to nucleotide 175 of the DPD gene sequence, and DELR1, which hybridizes to nucleic acids corresponding to nucleotide 563 to nucleotide 542 of the DPD gene sequence as described in Figure 1. It is important to note that other 15-20 nucleotide sequences within 500 nucleotides of the point mutation are also acceptable. Given the sequence of the affected exon, adjacent introns, and adjacent additional exons provided herein, selecting and making alternate primers is within the skill of a skilled practitioner in the relevant art.

The present invention also provides kits for the detection of genetic polymorphisms or mutations associated with DPDD. The kits comprise a vial containing amplification primers that span a DPDD-associated polymorphism or mutation in the gene encoding DPD. For example, the vial optionally contains DELF-1 and DELR-1. The kits  
5 optionally contain a vial containing a thermostable polymerase, genetic size markers for gels, amplification reagents, instructions and the like.

#### Sequence analysis of Amplification Products

A variety of methods are employed to analyze the nucleotide sequence of the  
10 amplification products. Several techniques for detecting point mutations following amplification by PCR have been described in Chehab *et al.*, *Methods in Enzymology*, 216:135-143 (1992); Maggio *et al.*, *Blood*, 81(1):239-242 (1993); Cai and Kan, *Journal of Clinical Investigation*, 85(2):550-553 (1990) and Cai *et al.*, *Blood*, 73:372-374 (1989).

One particularly useful technique is analysis of restriction enzyme sites  
15 following amplification. In this method, amplified nucleic acid segments are subjected to digestion by restriction enzymes. Identification of differences in restriction enzyme digestion between corresponding amplified segments in different individuals identifies a point mutation. Differences in the restriction enzyme digestion is commonly determined by measuring the size of restriction fragments by electrophoresis and observing differences  
20 in the electrophoretic patterns. Generally, the sizes of the restriction fragments is determined by standard gel electrophoresis techniques as described in Sambrook, and, *e.g.*, in Polymeropoulos *et al.*, *Genomics*, 12:492-496 (1992).

The size of the amplified segments obtained from affected and normal individuals and digested with appropriate restriction enzymes are analyzed on agarose or  
25 polyacrylamide gels. Because of the high discrimination of the polyacrylamide gel electrophoresis, differences of small magnitude are easily detected. Other mutations resulting in DPDD-related polymorphisms of DPD encoding genes also add unique restriction sites to the gene that are determined by sequencing DPDD-related nucleic acid sequences and comparing them to normal sequences.

30 Another useful method of identifying point mutations in PCR amplification products employs oligonucleotide probes specific for different sequences. The oligonucleotide probes are mixed with amplification products under hybridization

conditions. Probes are either RNA or DNA oligonucleotides and optionally contain not only naturally occurring nucleotides but also analogs such as digoxigenin dCTP, biotin dCTP, 7-azaguanosine, azidothymidine, inosine, or uridine. The advantage of using nucleic acids comprising analogs include selective stability, resistance to nuclease activity, ease of signal attachment, increased protection from extraneous contamination and an increased number of probe-specific colored labels. For instance, in preferred embodiments, oligonucleotide arrays are used for the detection of specific point mutations as described below.

Probes are typically derived from cloned nucleic acids, or are synthesized chemically. When cloned, the isolated nucleic acid fragments are typically inserted into a replication vector, such as lambda phage, pBR322, M13, pJB8, c2RB, pcos1EMBL, or vectors containing the SP6 or T7 promoter and cloned as a library in a bacterial host. General probe cloning procedures are described in Arrand J.E., *Nucleic Acid Hybridization A Practical Approach*, Hames B.D., Higgins, S.J., Eds., IRL Press 1985, pp. 17-45 and Sambrook, J., Fritsch, E.F., Maniatis, T., *Molecular Cloning A Laboratory Manual*, Cold Spring Harbor Press, 1989, pp. 2.1-3.58, both of which are incorporated herein by reference.

Oligonucleotide probes and primers are synthesized chemically with or without fluorochromes, chemically active groups on nucleotides, or labeling enzymes using commercially available methods and devices like the Model 380B DNA synthesizer from Applied Biosystems, Foster City, California, using reagents supplied by the same company. Oligonucleotides for use as probes, e.g., in *in vitro* amplification methods, or for use as gene probes are typically synthesized chemically according to the solid phase phosphoramidite triester method described by Beaucage and Caruthers (1981), *Tetrahedron Lett.*, 22(20):1859-1862, e.g., using an automated synthesizer, as described in Needham-VanDevanter *et al.* (1984) *Nucleic Acids Res.*, 12:6159-6168. Oligonucleotides can also be custom made and ordered from a variety of commercial sources known to persons of skill. Purification of oligonucleotides, where necessary, is typically performed by either native acrylamide gel electrophoresis or by anion-exchange HPLC as described in Pearson and Regnier (1983) *J. Chrom.* 255:137-149. The sequence of the synthetic oligonucleotides can be verified using the chemical degradation method of Maxam and

Gilbert (1980) in Grossman and Moldave (eds.) Academic Press, New York, *Methods in Enzymology* 65:499-560.

Oligonucleotide probes and primers are selected using commercially available computer programs to compare known DNA sequences from gene sequences found in gene libraries, such as Genbank and EMBL, and the sequences described herein. The programs identify unique nucleotide sequences within the gene of interest. One such program is Eugene. Oligonucleotide sequences for PCR of a unique genomic DNA such as a chromosome subsequence are chosen optimally by choosing sequences according to previously established protocols or by computer programs that choose the degree of homology desired along with the length of the probe. Sequences are chosen to avoid technical problems such as primer dimers resulting from amplification of hybridized primers.

Primers and probes are optionally labeled with fluorophores or enzymes that generate colored products. This allows simultaneous use of probes to different DPDD-related polymorphisms or mutations. Identification of hybridization of a specifically labelled primer provides a means for determining which polymorphism or mutation is present in the nucleic acid of the sample. The primers used in the assay are labeled with more than one distinguishable fluorescent or pigment color. Primers are labeled with Texas red, rhodamine and its derivatives, fluorescein and its derivatives, dansyl, umbelliferone and the like or with horse radish peroxidase, alkaline phosphatase, biotin, avidin, or the like.

Primers and probes are labeled directly or indirectly. The common indirect labeling schemes covalently bind a ligand to the nucleotide and prepare labeled probe by incorporating the ligand using random priming or nick translation. The ligand then binds an anti-ligand which is covalently bound to a label. Ligands and anti-ligands vary widely. When a ligand has an anti-ligand, e.g., biotin, thyroxine, or cortisol, the ligand is used in conjunction with the labelled naturally-occurring anti-ligand. Alternatively, a hapten or antigen may be used in combination with an antibody, which is optionally labeled.

Sequence specific oligonucleotide probes hybridize specifically with a particular segment of the target polymorphism or mutation amplification products and have destabilizing mismatches with the sequences from other polymorphisms or mutations. Under sufficiently stringent hybridization conditions, the probes hybridize specifically only

to exactly complementary sequences. The stringency of the hybridization conditions can be relaxed to tolerate varying amounts of sequence mismatch. Detection of the amplified product utilizes this sequence-specific hybridization to insure detection of only the correct amplified target, thereby decreasing the chance of a false positive caused by the presence of homologous sequences from related polymorphisms or mutations.

Specific DPD-encoding polymorphisms or mutations are also identified by sequencing the amplification products or restriction fragments thereof. Sequencing is performed by a variety of methods well known in the art. For example, the sequence of the amplified nucleic acid segments may be determined by the Maxam-Gilbert chemical degradation method as described in Sambrook. Generally, Sanger dideoxy-mediated sequencing is employed as described in Sambrook, or sequencing by hybridization is performed as described below.

#### Detection of Splicing Site Defects Using Nucleic acid Arrays

In one preferred class of embodiments, splicing site defects at intron-exon boundaries are detected by hybridization of amplification products which include the splicing site to oligonucleotide arrays which discriminate single base-pair mismatches. In this embodiment, primers are used to amplify an intron-exon boundary in a PCR reaction, resulting in PCR amplicons which comprise the intron-exon boundary. The sequence of the entire PCR amplicon, or any subsequence thereof can be determined by labeling the PCR amplicon (typically with biotin or a fluorescent label) and hybridization to an array of oligonucleotide probes. In these hybridization methods single base pair mismatches in labeled nucleic acids to probes in the array are distinguished.

Preferably in this class of embodiments, the oligonucleotide arrays are designed to sequence nucleic acids at the intron-exon boundary. More preferably, the arrays are designed to discriminate whether a particular nucleotide is altered relative to the wild-type sequence. This is done by constructing an array with two or more oligonucleotide probe sets which differ by a single nucleotide. Hybridization to the known probe sequence by a target nucleic acid under conditions where a single mismatch does not bind indicates the presence of a fully complementary nucleic acid.

Sequencing by hybridization to arrays of oligonucleotides is described in U.S. Patent No. 5,202,231, to Drmanac *et al.* and, *e.g.*, in Drmanac *et al.* (1989)

Genomics 4:114-128. Methods of constructing and designing arrays for sequencing and detection of single nucleotide alterations is known in the art. The development of very large scale immobilized polymer synthesis (VLSIPS™) technology provides methods for arranging large numbers of oligonucleotide probes for the detection and sequencing of nucleic acids in very small arrays. See, WO 90/15070 and 92/10092; Pirrung *et al.*, U.S. Patent No. 5,143,854 (see also PCT Application No. WO 90/15070); McGall *et al.*, U.S. Patent No. 5,412,087; and US Pat. No. 5,384,261. See also, Fodor *et al.* (1991) Science, 251: 767-777 and Sheldon *et al.* (1993) Clinical Chemistry 39(4): 718-719. The oligonucleotide arrays are typically placed on a solid surface such as a glass slide with an area less than 1 inch<sup>2</sup>, although much larger surfaces are optionally used.

Mechanical and Light directed oligonucleotide array construction methods are used for the construction of oligonucleotide arrays. Light directed methods are the most common, and are found, *e.g.*, in U.S. Patent No. 5,143,854. The light directed methods discussed in the '854 patent typically proceed by activating predefined regions of a substrate or solid support and then contacting the substrate with a preselected monomer solution. The predefined regions are activated with a light source, typically shown through a photolithographic mask. Other regions of the substrate remain inactive because they are blocked by the mask from illumination. Thus, a light pattern defines which regions of the substrate react with a given nucleic acid reagent. By repeatedly activating different sets of predefined regions and contacting different reagent solutions with the substrate, a diverse array of oligonucleotides is produced on the substrate. Other steps, such as washing unreacted reagent solutions from the substrate, are used as necessary.

The surface of a solid support is typically modified with linking groups having photolabile protecting groups and illuminated through a photolithographic mask, yielding reactive hydroxyl groups in the illuminated regions. For instance, during oligonucleotide synthesis, a 3'-O- phosphoramidite (or other nucleic acid synthesis reagent) activated deoxynucleoside (protected at the 5'-hydroxyl with a photolabile group) is then presented to the surface and coupling occurs at sites that were exposed to light in the previous step. Following capping, and oxidation, the substrate is rinsed and the surface illuminated through a second mask, to expose additional hydroxyl groups for coupling. A second 5'-protected, 3'-O-phosphoramidite activated deoxynucleoside (or other monomer as appropriate) is then presented to the resulting array. The selective photodeprotection

and coupling cycles are repeated until the desired set of oligonucleotides (or other polymers) is produced.

The PCR amplicons detected on the arrays are labeled with a composition detectable by spectroscopic, photochemical, biochemical, immunochemical, or chemical means. For example, useful labels include <sup>32</sup>P, <sup>35</sup>S, fluorescent dyes, chromophores, electron-dense reagents, enzymes (e.g., as commonly used in an ELISA), biotin, dioxigenin, or haptens and proteins for which antisera or monoclonal antibodies are available. In preferred embodiments, the label is detectable spectroscopically, *i.e.*, is chromogenic. Suitable chromogens include molecules and compounds which absorb light in a distinctive range of wavelengths so that a color may be observed, or emit light when irradiated with radiation of a particular wavelength or wavelength range (e.g., a fluorescent label).

### EXAMPLES

The following examples are offered by way of illustration and not limitation. One of skill will readily recognize a variety of parameters and conditions which can be changed or modified to yield essentially identical results.

The following example pinpoints a polymorphism or "mutation" of the gene encoding DPD that is associated with DPDD, and provides a novel method for the efficient detection of this DPDD splicing mutation.

#### Example 1

The PCR reaction is performed using human genomic DNA obtained from fibroblast cultures of 5 members of a family, one of which was afflicted with DPDD.

The PCR primers were selected so as to bracket the exon that is not present in the DPDD gene and part of the two introns on either side of this exon. Primers were synthesized using an Applied Biosystems 394 DNA & RNA synthesizer. The forward primer was DELF1, which encompassed nucleotide 154 to nucleotide 175 of the DPFD gene sequence and had the sequence TGCAAATATGTGAGGAGGGACC (*see also* Figure 1 and Figure 2). The reverse primer was DELR1, which encompassed nucleotide 563 to nucleotide 542 of the DPFD gene sequence and had the sequence CAAAGCAACTGGCAGATTC (*see also* Figure 1 and Figure 2). PCR was carried out in

50  $\mu$ l of a reaction mixture consisting of 10 mM Tris-HCl pH 8.3, 50 mM KCl, 2.5 mM MgCl<sub>2</sub>, 0.5 mM dNTPs, 1  $\mu$ M of each primer, and 2.5 units *Taq* polymerase (Roche Molecular Systems) for 30 cycles denaturing at 96°C for 1 min, annealing at 55°C for 1 min, and extending at 72°C for 2 min. The amplified products were extracted with 1  
5 volume of chloroform and purified by filtration through Centricon 100 filter units.

Typically, one-fifth of the purified PCR product was used for sequence analyses with an Applied Biosystems 373A automated sequencer and fluorescent dye-deoxy terminator chemistry. Sequence data were analyzed using the MacVector sequence analysis software (International Biotechnology).

10 The PCR fragments were analyzed by electrophoresis in a 1% agarose gel stained with ethidium bromide. For Southern blot analysis, the DNA in the gels were depurinated by a 20-min incubation in 200 mM HCl and denatured by a 20-min incubation in 0.5 M NaOH. The DNA was transferred to Gene Screen Plus nylon membranes (New England Nuclear) overnight in 0.5 M NaOH, and was fixed to the filter by baking for 90  
15 min at 80°C. Prehybridization was done in a solution of 6 x SSC, Denhardt's reagent, 0.5% NaDodSO<sub>4</sub>, and 0.2 mg/ml sonicated salmon sperm DNA at 65°C for 3 hr, then hybridization was carried out overnight at 65°C in the same solution containing 1.5 x 10<sup>6</sup> cpm/ml of <sup>32</sup>P random priming-labeled human DPD, cDNA. After washing at 65°C for 20 min in 2 x SSC, 0.5% NaDodSO<sub>4</sub>, and 45 min in 0.1 x SSC, 0.5% NaDodSO<sub>4</sub> at  
20 65°C, the membranes were exposed to X-ray film (Eastman Kodak Co.) at -80°C for 30 min.

The results of sequencing the various genomic DNAs reveal the presence of a G to A mutation at position 434. This mutation was located within the splice site. The DPDD patient was homozygous for this mutation. Both parents and one sibling were  
25 heterozygous and another was homozygous for the normal allele.

The G to A mutation resulted in the destruction of a restriction site recognized by restriction endonucleases which recognize the Mae II binding sequence, ACGT. Consequently, after PCR amplification of genomic DNA using the primers

DELF1 and DELR1, digestion of the resulting PCR product with a restriction endonuclease that cleave the MaeII site yields fragments having the following sizes:

<u>Normal allele</u>	<u>Mutant allele</u>
278 + 131 bp	408 bp

5

**Example 2: Identification of a Polymorphism which causes DPDD**

**Family pedigree**

Blood samples from a British family were collected after a family member displayed excessive 5-FU toxicity during chemotherapy. This family is unrelated to any family with DPD deficiency that has previously been reported. To screen for the presence of the mutation leading to the deficiency in the normal population, genomic DNA was collected from healthy subjects representing the following ethnic groups: Caucasians (English and Finnish), Asians (Japanese and Taiwanese) and African-Americans.

**DPD catalytic activity.**

DPD catalytic activity for the family under study was determined from peripheral blood mononuclear cells using a previously described HPLC method (McMurrough *et al.* (1996) *Br. J. Clin. Pharmacol.*). In brief, peripheral blood mononuclear cells were purified from the patient's blood in a density gradient using Ficoll-Hypaque (Pharmacia, Upsala) and incubated for 90 min with [<sup>14</sup>C]-5 FU. The production of 5-FU metabolites were then quantified by HPLC analysis by radiodetection.

20

**Isolation of RNA and RT-PCR.**

Total RNA was isolated from peripheral blood mononuclear cells by the guanidinium thiocyanate-phenol-chloroform method (Chomezynski *et al.* (1987) *Anal. Biochem.* 162: 156-159). The RNA solutions were dissolved in DEPC-treated water and stored at -80°C until use. RT-PCR was performed as described (Meinsma *et al.* (1995) *DNA Cell. Biol.* 14: 1-6) and the products were analyzed by electrophoresis in 0.8% agarose gels and visualized by staining with ethidium bromide.

25

**Cloning and characterization of the genomic fragment encoding the deleted exon.**

The DPD cDNA was used as a probe to isolate a P1 clone containing about 100 kbp of the human *DPD* gene (PAC 5945) from a high density PAC human genomic library (Genome Systems, St. Louis, MO). Southern blotting was used to confirm that the P1 clone contained the deleted exon using a probe located within the deleted fragment.

30

This probe was synthesized from the DPD cDNA by using the primers: DPD15

(forward): 5' TGTGACAAATGTTTCCC 3' and DPD15R (reverse): 5'

AGTCAGCCTTTAGTTCAGTGACAC 3' to specifically amplify the putative exon. PCR conditions were as indicated below but extension was carried out at 72°C for 1 min. This

- 5 PCR fragment was purified using a Wizard PCR purification kit (Promega, Madison, WI), labeled with [ $\alpha^{32}$ P]-dCTP and hybridized with the clone PAC 5945. DNA was purified from this genomic clone using Qiagen columns (Qiagen, Chatsworth, CA), and the 5' and 3' ends of the deleted exon and adjacent intronic regions were sequenced by chromosome walking from within the deleted exon using dideoxy terminator chemistry and an ABI
- 10 373A DNA sequencer (Applied Biosystems, Foster City, CA). The intronic sequences obtained allowed the selection of appropriate primers (e.g., delF1 and delR1) to amplify from genomic DNA the complete exon and immediate flanking intronic sequences. All primers used in this study were synthesized with a 391 DNA&RNA synthesizer (Applied Biosystems, Foster City, CA).

15 **Genotyping of the mutant *DPD* allele.**

A 409 bp PCR genomic fragment corresponding to the deleted exon (from G1822 to C1986 in Yokota, *et al.* (1994) *J. Biol. Chem.* 269: 23192-23196) plus the flanking intronic sequences containing the AG and GT splicing consensus sequences was amplified from human genomic DNA using the primers delF1 (forward) 5'

- 20 TGCAAATATGTGAGGAGGGACC 3' and delR1 (reverse) 5'

CAGCAAAGCAACTGGCAGATTC 3'. PCR amplification was carried out in a 100  $\mu$ l reaction mixture containing 10 mM Tris-HCl (pH 8.3), 50 mM KCl, 1.5 mM MgCl<sub>2</sub>, 0.2 mM of each dNTP, 0.5  $\mu$ M of each primer, 2.5 units of *Taq* Polymerase (Roche

- Molecular Systems) and 500 ng of genomic DNA template for 31 cycles by denaturing at
- 25 94°C for 1 min, annealing at 60°C for 1 min and extending at 72°C for 2 min. Subjects identified as wild type, heterozygous or homozygous for the splicing mutation could be distinguished by digesting the PCR product with the restriction endonuclease *Mae* II (Boehringer, Mannheim, Indianapolis, IN) and electrophoresis in 1% regular, 3% NuSieve agarose gels (FMC Bioproducts, Rockland, ME). The genotypes obtained were verified
- 30 by sequencing the 409 bp PCR product. The sources of the genomic DNA samples for the different ethnic groups correspond to those previously described (Fernandez-Salguero *et al.* (1995) *Am. J. Hum. Genet.* 57: 651-660).

**DPD catalytic activity.**

To determine DPD catalytic activities in the proband and family members, lymphocytes were isolated and subjected to analysis by HPLC (McMurrough *et al.* (1996) *Br. J. Clin. Pharmacol.*). Activities ranged between 24% to 70% of the mean DPD activity determined in the normal population (155 pmole/min/mg protein) (Table 1). It should be noted that all the subjects in the pedigree presented a relatively low catalytic activity (below 70% of the mean in the normal population). Subject II, a cancer patient who exhibited 5-FU toxicity, had catalytic activity which was 24% of the mean population.

**RT-PCR analysis.**

RT-PCR was performed on total RNA isolated from peripheral blood mononuclear cells corresponding to each of the members of the pedigree shown in Figure 1. The full length coding region of the DPD cDNA was amplified in three fragments of 1.5 kbp, 906 bp and 919 bp. The 1.5 kbp and 906 bp PCR fragments were detected in all the members of the family and correspond to the normal mRNA as expected from the cDNA sequence. A 741 bp band corresponded to the deleted exon and was heterozygous with respect to the wild type 906 bp fragment. Sequencing of this 741 bp PCR fragment confirmed that a 165 bp deletion has occurred that precisely corresponds to that previously reported in a Dutch family (Meinsma *et al.* (1995) *DNA Cell. Biol.* 14: 1-6). No homozygous mutant subjects were found in this pedigree. The generation of the mutant mRNA is illustrated in Figure 3. Faulty splicing is the mechanism for the generation of the shorter mRNA, which due to the absence of 55 amino acids would be unable to be translated into an intact DPD enzyme.

**Genomic DNA sequence analysis of the mutant DPD allele.**

A clone containing the deleted exon was isolated in a recombinant P1 phage. Sequence of the intronic regions flanking the deleted exon enabled the development of a PCR reaction to sequence the exon and across the 5' and 3' splicing sites. Sequence of the 409 bp PCR genomic fragment clearly indicated the presence of a G to A point mutation (GT to AT) at the 5' donor splice consensus sequence in the British pedigree in subjects II1, II2, II3, II4, II7, II8, II9, III6, III8 and III9. Subjects II1, II6, III1, III2, III4 and III7 were found to have two normal alleles. The subject previously reported to have the 165 bp deletion present in both alleles and his heterozygote brother (subjects 1 and 2 in Meinsma *et al.* reference) were also analyzed and found to possess the splicing mutation

present in both alleles for subject 1 and in one allele for subject 2. The G to A mutation correlates 100% with the corresponding RT-PCR results for the deletion of the entire exon, indicating that the CT to AT mutation in the 5' splicing consensus sequence of the *DPD* gene leads to skipping of the entire preceding exon. The genotypes and catalytic activities for this 5'-splicing mutation in the pedigree are summarized in Table I.

**Genotyping test for the mutant *DPD* allele and population screening.**

The 409 bp genomic PCR fragment containing the deleted exon has a restriction site for the endonuclease Mae II (A-CGT) which produces two fragments of 278 bp and 131 bp from the wild type allele. This site is eliminated when a G to A mutation occurs at the 5'-splicing site (A-CAT). A diagrammatic representation of the strategy developed for PCR amplification of the 409 bp fragment and the restriction enzyme pattern expected with MAE II is shown in Figure 4. The reliability of the genotyping assay was confirmed by sequencing the 409 bp PCR product in these samples. By analyzing normal subjects within different ethnic groups (Table II), we found that this mutant allele is present in the Finnish (4.4%) and Taiwanese (5.4%) populations where heterozygotes were detected. However, within the samples tested to date, no mutant alleles were found in 35 Japanese or 20 African-American subjects. All heterozygous subjects found by restriction enzyme analysis were also confirmed by genomic DNA sequence analysis.

**TABLE I: Relationship between phenotype and genotype for the DPD catalytic activity and the presence of the 5'-splicing mutation in the pedigree analyzed.**

	Family Member	DPD activity (%) <sup>*</sup>	Genotype <sup>†</sup>
5	I1	24	+/-
	II1	57	+/+
	II2	39	+/-
	II3	36	+/-
	II4	42	+/-

20	III6	36	+/-
	III7	70	+/+
	III8	31	+/-
	III9	56	+/-

25   <sup>\*</sup> DPD activity is expressed as percentage of the mean activity in the normal population.

<sup>†</sup> Genotype for the GT to AT splice mutation: +/+ : wild type; +/- : heterozygote; / : homozygote; n/d: not determined

**TABLE II: Allelic frequency for the presence of the 5'-splicing mutation in different ethnic groups from the normal population**

		Subject*	Wild type (+/+)	Heterozygote (+/-)	Homozygote (-/-)
5	Caucasian				
	British	30	100 (30) <sup>a</sup>	0 (0) <sup>a</sup>	0 (0) <sup>a</sup>
	Finnish	45	95.6 (43)	4.4 (2)	0 (0)
	Asian				
10	Taiwanese	37	94.6 (35)	5.4 (2)	0 (0)
	Japanese	35	100 (35)	0 (0)	0 (0)
	African-American	20	100 (20)	0 (0)	0 (0)

<sup>a</sup>The allelic frequency is indicated as a percentage of the total number of subjects analyzed. The absolute number of heterozygote subjects are indicated in parenthesis.

20

All publications, patents and patent applications mentioned in this specification are herein incorporated by reference into the specification to the same extent as if each individual publication, patent or patent application was specifically and individually indicated to be incorporated herein by reference.

25

Although the foregoing invention has been described in some detail by way of illustration and example for purposes of clarity of understanding, it will be obvious that certain changes and modifications may be practiced within the scope of the appended claims.

**WHAT IS CLAIMED IS:**

1. A method of detecting a splicing defect in a dihydropyrimidine dehydrogenase gene, comprising determining whether a genomic DNA encoding the dihydropyrimidine dehydrogenase gene has a wild-type intron-exon boundary for an exon which encodes amino acids 581-635 of a corresponding wild-type dihydropyrimidine dehydrogenase protein.
2. The method of claim 1, wherein the method comprises the step of amplifying intronic genomic DNA encoding the dihydropyrimidine dehydrogenase in the region flanking the exon which encodes amino acids 581-635.
3. The method of claim 2, wherein the method comprises amplifying the genomic DNA with a primer which hybridizes to a dihydropyrimidine dehydrogenase intronic nucleic acid which hybridizes to a primer selected from the group of primers consisting of DELF1, and DELR1 under stringent conditions.
4. The method of claim 2, wherein DNA amplified with the primers is cleaved with a restriction endonuclease which recognizes a Mae II cleavage site.
5. The method of claim 1, wherein the sequence of the intron-exon boundary is determined using an oligonucleotide array.
6. A method of screening patients for sensitivity to 5-fluorouracil, comprising isolating a genomic DNA from the patient which encodes the dihydropyrimidine dehydrogenase gene and determining whether the gene has a wild-type intron-exon boundary for an exon which encodes amino acids 581-635 of a corresponding wild-type dihydropyrimidine dehydrogenase protein.
7. The method of claim 6, wherein the method comprises the step of amplifying intronic genomic DNA encoding the dihydropyrimidine dehydrogenase in the region flanking the exon which encodes amino acids 581-635.

8. The method of claim 7, wherein the method comprises amplifying the genomic DNA with a primer which hybridize to a dihydropyrimidine dehydrogenase intronic nucleic acid which hybridizes to a primer selected from the group of primers consisting of DELF1 or DELR1 under stringent conditions.

5

9. The method of claim 7, wherein DNA amplified with the primers is cleaved with a restriction endonuclease which recognizes a Mac II cleavage site.

10. A composition comprising a first PCR primer which binds to DNA 3' of a splice site in the genomic DNA for dihydropyrimidine dehydrogenase gene for an exon encoding amino acids 581-635, and a second PCR primer which binds to DNA 5' of a splice site in the genomic DNA for dihydropyrimidine dehydrogenase gene for an exon encoding amino acids 581-635.

11. The composition of claim 10, wherein the first PCR primer binds to intronic dihydropyrimidine dehydrogenase DNA.

12. The composition of claim 10, wherein the second PCR primer binds to intronic dihydropyrimidine dehydrogenase DNA.

20

13. The composition of claim 10, wherein the first PCR primer hybridizes under stringent conditions to a nucleic acid complementary to DELF1.

14. The composition of claim 10, wherein the second PCR primer hybridizes under stringent conditions to a nucleic acid complementary to DELR1.

15. A kit comprising a container, a first PCR primer which binds to DNA 3' of a splice site in the genomic DNA for dihydropyrimidine dehydrogenase gene for an exon encoding amino acids 581-635, and a second PCR primer which binds to DNA 5' of a splice site in the genomic DNA for dihydropyrimidine dehydrogenase gene for an exon encoding amino acids 581-635.

30

16. The kit of claim 15, wherein the kit further comprises instructions for the detection of splicing site defects in the dihydropyrimidine dehydrogenase gene.

17. The kit of claim 15, wherein the kit further comprises *Mae* II.

5

18. The composition of claim 15, wherein the first PCR primer hybridizes under stringent conditions to a nucleic acid complementary to DELF1.

19. The composition of claim 15, wherein the second PCR primer  
10 hybridizes under stringent conditions to a nucleic acid complementary to DELR1.

# INTERNATIONAL SEARCH REPORT

International Application No  
PCT/US 97/04269

A. CLASSIFICATION OF SUBJECT MATTER  
IPC 6 C12Q1/68

According to International Patent Classification (IPC) or to both national classification and IPC

## B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

IPC 6 C12Q

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

## C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category *	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
Y	DNA AND CELL BIOLOGY, vol. 14, no. 1, January 1995, page 1-6 XP000675568 MEINSMA ET AL: "Human polymorphism in drug metabolism: mutation in the dihydropyrimidine dehydrogenase gene results in exon skipping and thymine uracilurea" cited in the application see abstract and paragraph 1, page 5. --- -/--	1-19

☒ Further documents are listed in the continuation of box C.

☐ Patent family members are listed in annex.

### \* Special categories of cited documents:

- \*A\* document defining the general state of the art which is not considered to be of particular relevance
- \*E\* earlier document but published on or after the international filing date
- \*L\* document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- \*O\* document referring to an oral disclosure, use, exhibition or other means
- \*P\* document published prior to the international filing date but later than the priority date claimed

- \*T\* later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
- \*X\* document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
- \*Y\* document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.
- \*&\* document member of the same patent family
